Need support?The present invention relates generally to a method of detecting and measuring blood loss in patients and, more particularly, to a method of detecting and measuring blood loss after cardiac or abdominal surgery in which a separable portion of the patient's blood supply is artificially blocked and circulating blood is returned to the patient's blood supply. A wide variety of procedures have been developed for artificially blocking off a portion of the blood supply in patients to eliminate blood loss. For example, after a patient suffers a heart attack, it is often necessary to block off a blood supply to a heart in the patient's chest to allow the heart to rest. It is also known to block off the blood supply to an arm of a patient to allow the patient to receive a blood transfusion. It is also known to block off the blood supply to both legs of a patient to allow the patient to receive a blood transfusion. Typically, the procedures for blocking off the blood supply in a patient's chest include withdrawing a blood supply from the patient, inserting a cannula into a vein in the patient's body, and withdrawing blood from the patient's chest into the cannula through the vein in the patient's body. In withdrawing the blood supply, a male cannula is placed within a female cannula to allow blood to flow from the female cannula to the male cannula. The procedure for blocking off the blood supply in the arms of a patient also includes withdrawing a blood supply from the patient, inserting a separable portion of the cannula into a vein in the patient's body, and withdrawing blood from the patient's arms into the separable portion of the cannula. The separation of the male and female cannulas may be accomplished by surgically separating the second and third portions of the arterial wall at the end of the radial and ulnar arteries in the hand and forearm
